# What are cosmic rays ?

= high-energy, extraterrestrial particles

**Warning:**

**c. 100.000 particles will pass your body in each 1 hour !!**

**primary cosmic rays:**

fully ionised atoms 98%

(mainly Hydrogen and Helium nuclei)

<1% Electrons

<1% Photons

**secondary cosmic rays:**

high energy particles generated in the atmosphere by primary cosmic rays

# Charged Cosmic Rays: the energy spectrum

← 1 particle per  $\text{m}^2 \text{ s}$

← 1 particle per  $\text{m}^2 \text{ year}$

← 1 particle per  $\text{km}^2 \text{ year}$

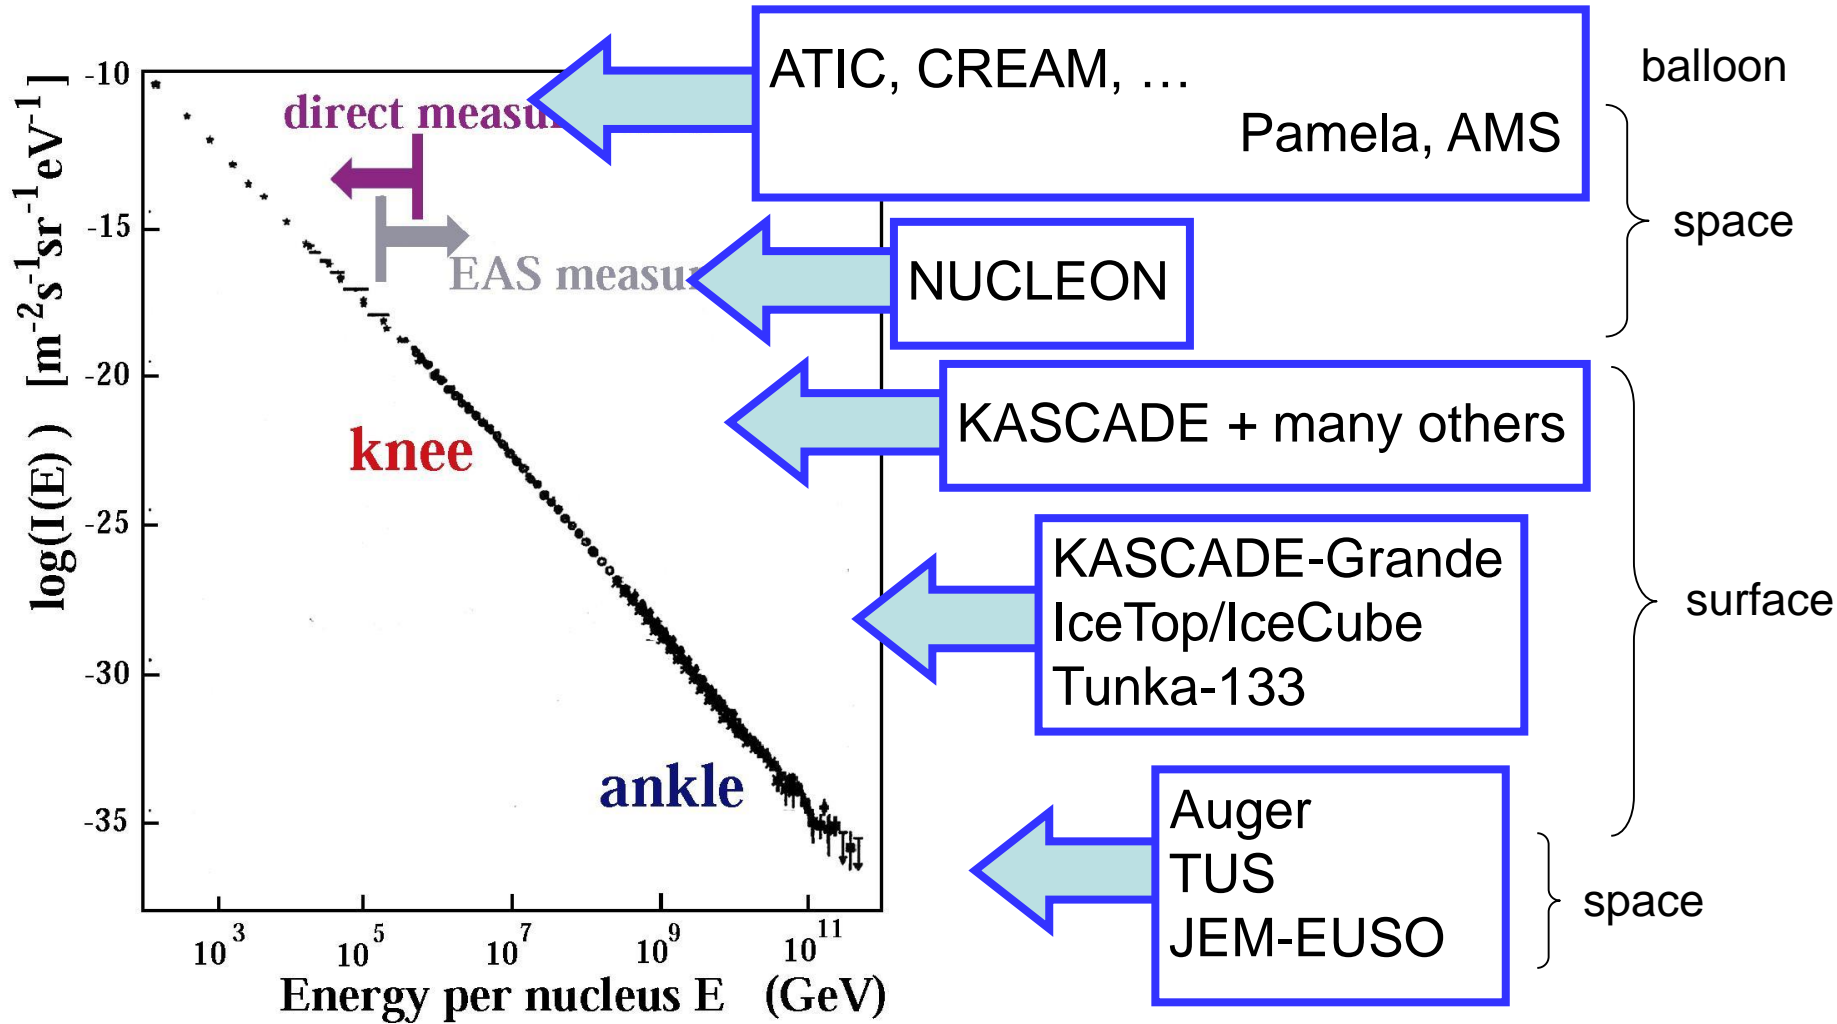

above  $10^{14}$  eV : Only indirect measurements possible !

# Charged Cosmic Rays: the energy spectrum

intergalactic medium

# Cosmic Rays: Power of the sources?

Estimate of the energy density of cosmic rays:

$$\rho = 1 \text{ eV/cm}^3$$

Which power is needed to keep this energy density ?

$$L = V \rho / \tau \approx 5 \cdot 10^{40} \text{ erg/s}$$

With  $V$  as volume of our Galaxy (300pc thick, radius 15kpc) and  $\tau$  = time of the particles in the volume:  $6 \cdot 10^6$  years

e.g.:

Supernovae:  $10^{51}$  erg/s energy release, 1 SN per 30 years and 10% efficiency in cosmic rays

**CR likely galactic origin!**

similar power values:

star winds of red super giants  
=  $10^{50}$  erg/s (problem: efficiency)  
or pulsars or binary systems

$$1 \text{ erg} = 10^{-7} \text{ J} = 100 \text{ nJ}$$

$$1 \text{ erg} = 624.15 \text{ GeV} = 6.2415 \times 10^{11} \text{ eV}$$

$$1 \text{ erg} = 1 \text{ g} \cdot \text{cm}^2/\text{s}^2$$

# Cosmic Rays: Sources?

## Galactic Sources:

- Supernovae
- Supernova remnants
- Star formation regions ?

# Cosmic Rays: Acceleration? : general remarks

## Acceleration in magnetic fields

## Acceleration at shock fronts (Fermi-Acceleration)

The acceleration mechanisms requires following conditions:

1.) power law dependence of all particle types

$$dN(E) \propto E^{-x} dE \quad \text{with } x=2.2-3$$

2.) energies up to  $10^{20}$  eV

3.) elemental composition similar to solar abundances

problem: storage period of particles in the acceleration zone have to be long (e.g. synchrotron) and the zone have to be stable.

# Cosmic Rays: Fermi Acceleration

## Fermi-mechanism 1st order at strong shock waves

simple calculation in lab system:

shock front with velocity  $V$  and  
gas behind with velocity  $U$  →

$$\Delta E_1 = \frac{1}{2} m (\mathbf{v} + (\mathbf{V} - \mathbf{U}))^2 - \frac{1}{2} m v^2$$

$$= \frac{1}{2} m (2\mathbf{v}(\mathbf{V}-\mathbf{U}) + (\mathbf{V}-\mathbf{U})^2)$$

with  $v \gg V, U$  and  $V > U$

→ always head-on collisions!

→ energy gain

$$\Delta E/E = 2 (V-U) / v$$

relativistic calculations and taking  
Into account the scatter angles:

$$\rightarrow \Delta E/E = 4/3 (V-U) / c$$

→ classical kinematic describes how often particles pass the shock

→ escape probability is similar to the energy gain:  $P \approx \epsilon$ .

$$\rightarrow N(E) dE \propto E^{-2} dE \quad !!!$$

(strong shocks are observed at supernova remnants)

(a) Shock front traveling at speed  $U$

(c) rest frame of downstream medium

(b) seen in rest frame of shock front

(d) rest frame of upstream medium

# Cosmic Rays: Acceleration > 100 TeV ?

## idea: acceleration in Pulsars

### Pulsar:

- remnant of a supernova explosion
- radius 10 km, density  $6 \cdot 10^{13} \text{g/cm}^2$  (density of nuclei) (neutron stars, decay of n are stopped)
- creation by gravity collaps but with conservation of the angular momentum:

→  $T_{\text{Pulsar}} = 1 - 30 \text{ ms}$

→ very high magnetic fields:

$B_{\text{Star}} = 0.1 \text{ Tesla}$  →

$B_{\text{Pulsar}} = 2.5 \cdot 10^8 \text{ Tesla}$

→ very strong electrical fields by induction

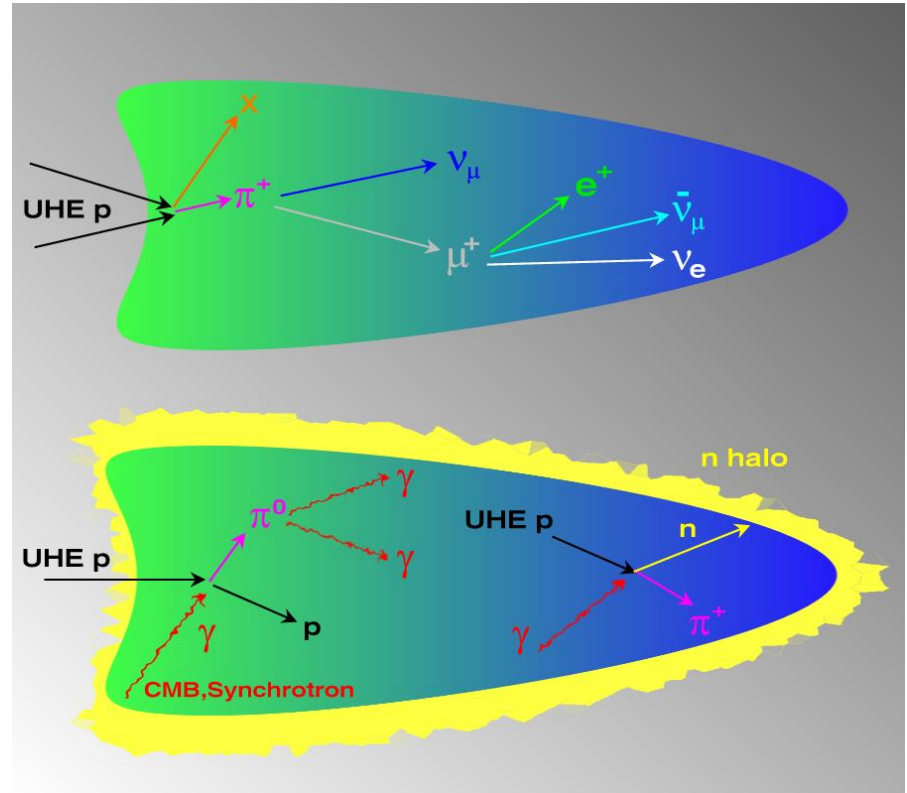

# Cosmic Rays: Acceleration > 100 TeV ?

idea: acceleration in AGN:

Centaurus A, HST optical and radio

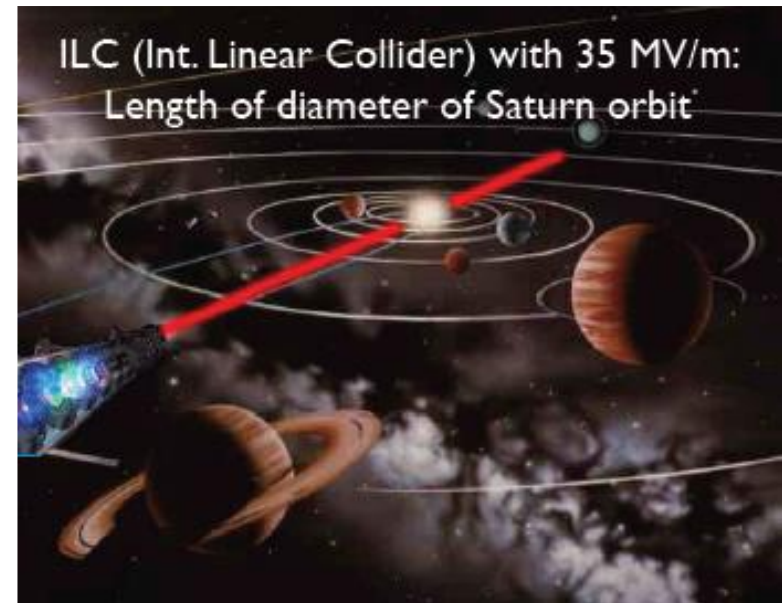

problem: interaction of the accelerated particles inside the jet

TeV- gamma radiation from AGN's are observed (timely and spectral very variable)

# Cosmic Rays: Transport

## Transport through interstellar/intergalactic medium

**Density at the interstellar medium:**

**1 particle per  $\text{cm}^3$**

**Density at the intergalactic medium:**

**6 particles per  $\text{m}^3$**

# Cosmic Rays: Transport

## content of the ISM:

-) clouds

-neutral or ionised H(He..)-gas

-density  $\rho=10^{-24}$  g/cm<sup>3</sup>

-interactions by particle collisions

-) magnetic fields

$B=1-3$   $\mu$ G

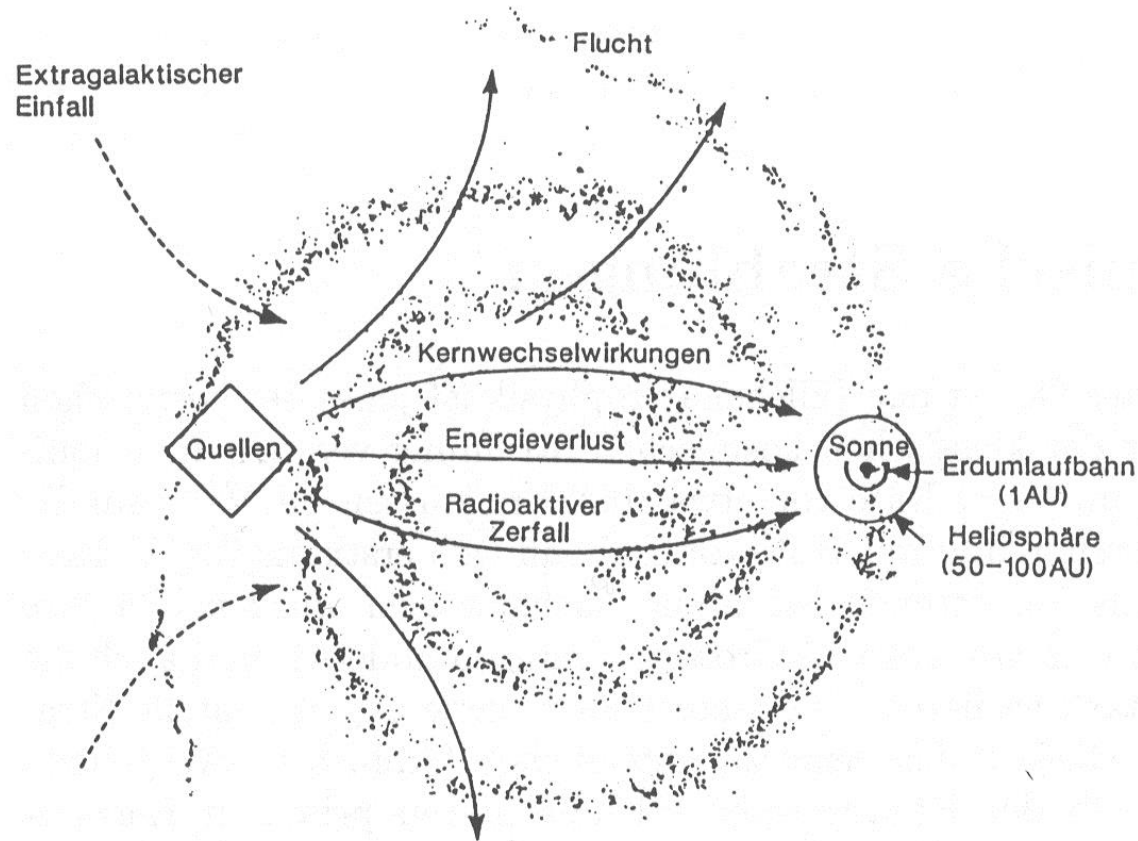

diffusion

-) microwave background

$2.7\text{K} = 2.3 \cdot 10^{-4}$  eV

$= 5.6 \cdot 10^{10}$  Hz  $= 5 \cdot 10^{-3}$  m

Interactions by photo-pion production (= GZK)

# Cosmic Rays: Transport Equation

Diffusion equation for relativistic particles:

$$dN_i/dt = d/dE[b_i(E)N_i(E)] + Q_i + \nabla(D_i \nabla N_i)$$

$N_i = N_i(E, x, t) dE$  = number (density) of a specific particle  $i$   
at the position  $x$  and time  $t$  in the energy range  $E+dE$

$Q_i$  = injection rate of these particles into a volume  $dV$

The particle gains (-) or loses (+) energy as  $-(dE/dt)=b(E)$

→  $dN(E)/dt = d/dE[b(E)N(E)]$  is the timely development of the particle spectrum

→ in the volume by energy gains and losses

additionally injection and escape to the volume by diffusion

(dependent on particle density  $N_i$ )

$$D = 1/3 \lambda v$$

$\lambda$  = free pathlength =  $10 \text{ g/cm}^2$  for protons in ISM =  $3 \text{ g/cm}^2$  for iron in ISM

# Cosmic Rays: Transport Equation

$$\frac{dN_i}{dt} = \frac{d}{dE}[b_i(E)N_i(E)] + Q_i + \nabla(D_i \nabla N_i) - N_i/\tau_i + \sum_{j>i} P_{ji}/\tau_j N_j$$

effects of spallation: change (+ or -) of  $N_i$

$\tau_i$  = lifetime of species  $i$   
(attention: Lorentz-Dilation: increases lifetime)

$P_{ji}$  = probability that a collision creates a species  $j$  out of species  $i$

→ explain the change of the slope from the source ( $\gamma=-2.0$ ) to observation ( $\gamma=-2.7$ )

All calculations are in good agreement with the assumption of a halo built with high-energetic particles !!

# Cosmic Rays: Transport: Leaky Box Model

## ‚Confinement‘ in our Galaxy:

- ) high energy particles pass ca.  $5\text{g/cm}^2$  matter (from comparisons of spallation calculations with Measurements at low energies, e.g. Cr/Fe-ratio)
- ) average density in our Galaxy:  $N = 10^{-6} \text{ m}^{-3}$

with  $\lambda = \rho \cdot c \cdot t \rightarrow$

$t_{\text{esc}} \approx 3 \cdot 10^6$  years

escape time from Milky Way

(or larger, if longer confinements in less dense regions)

← proof that particles have scrumpled pathes, as straight path would need only  $10^4$  years

Best description by the ‚Leaky Box Model‘

= free diffusion inside the box, reflections at the edge of the box

probability of transmission out of the box

$$dN / dt + N / t_{\text{esc}} = 0 \rightarrow N \propto \exp(-t / t_{\text{esc}})$$

# Cosmic Rays transport at highest energies: GZK Greisen-Zatsepin-Kuzmin Effect

**Pion photo production**  
( $E_p > 5 \times 10^{19} \text{ eV}$  due to CMB) :

**Interaction length  $\sim 6$  Mpc**  
**Energy loss  $\sim 20\%$  / interaction**

**$\rightarrow$  Nearby sources ( $< 50$  Mpc)**

**1 yr =  $9.46 \times 10^{15}$  m**  
**1 pc = 3.26 yr  $\sim \pi$  yr**

# Cosmic Rays: History - 1910

~1900: Electroscopes discharge, even if they are shielded from radioactive sources  
→ Rutherford: radioactivity at the walls, etc...

( $\gamma$ -radiation and its absorption coefficient was known → after 80m in air only 50% → Eiffeltower at 330m: no radiation)

~1910: Theodor Wulf  
→ at 330m: Ionisation decrease to 60%

Electrometer

The Jesuit padre Theodor Wulf clammers in the year 1910 the Paris Eiffel-Tower to find the source of the ionizing radiation in the Earth's Atmosphere.

# Cosmic Rays: History - 1912

**Victor Hess 1912:**  
**There are particles coming from ,outside‘  
(Cosmos)**

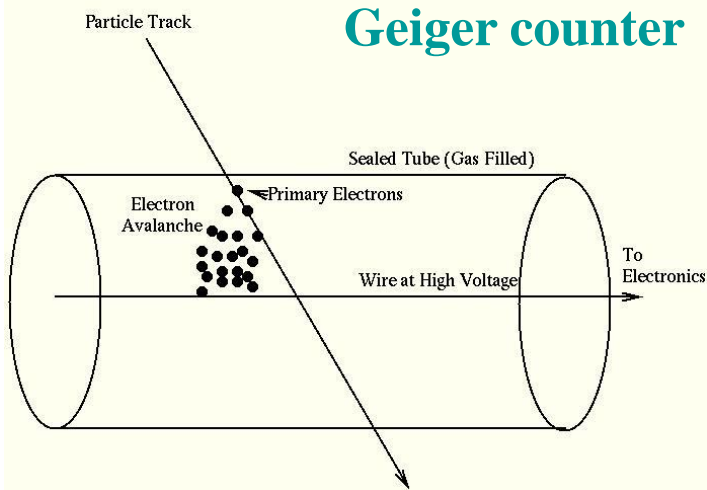

**Finding:**  
**Ionisation increase with height !**  
**(Hess reached 5000m)**

# Cosmic Rays: History – 1912-25

1936: coincidence measurements at the Jungfrauoch

Following years: separation of cosmic ray and particle (accelerator) physics

# Cosmic Rays: History - 1958

## The “first knee”

G.V.Kulikov & G.B.Khristiansen

Soviet Physics JETP Volume  
35(8), No 3, March 1959

measured  $N_{ch}$  spectra

hodoscope counters in a 20x20 m<sup>2</sup>  
array

„the observed spectrum is a  
superposition of the spectra of  
particles of galactic and  
metagalactic origin“

# Cosmic Rays: History - 1962

## The first event above $10^{20}$ eV

Volcano Ranch array,

New Mexico US

20 scintillators spaced in 147m

J. Linsley

Phys.Rev.Lett. 10 146-148,1963

FIG. 1. Plan of the Volcano Ranch array in February 1962. The circles represent  $3.3\text{-m}^2$  scintillation detectors. The numbers near the circles are the shower densities (particles/ $\text{m}^2$ ) registered in this event, No. 2-4834. Point "A" is the estimated location of the shower core. The circular contours about that point aid in verifying the core location by inspection.

# Extensive air showers

above  $10^{14}$  eV :

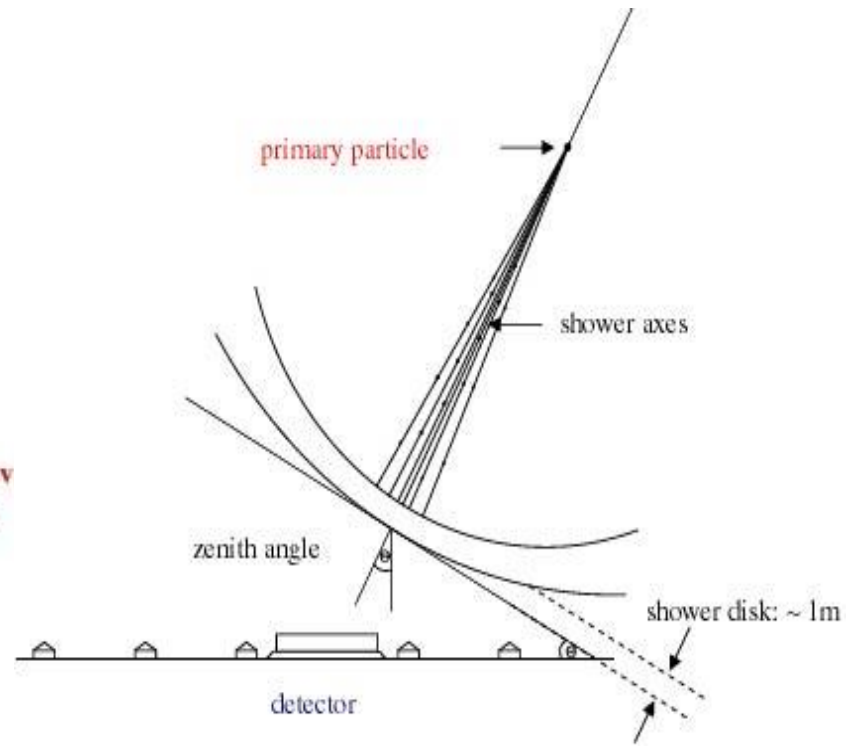

Only indirect measurements possible !

**EAS**

**Air shower interactions: Above all man-made energies for single particles and in extreme forward direction!**

# Extensive Air Showers - schematic

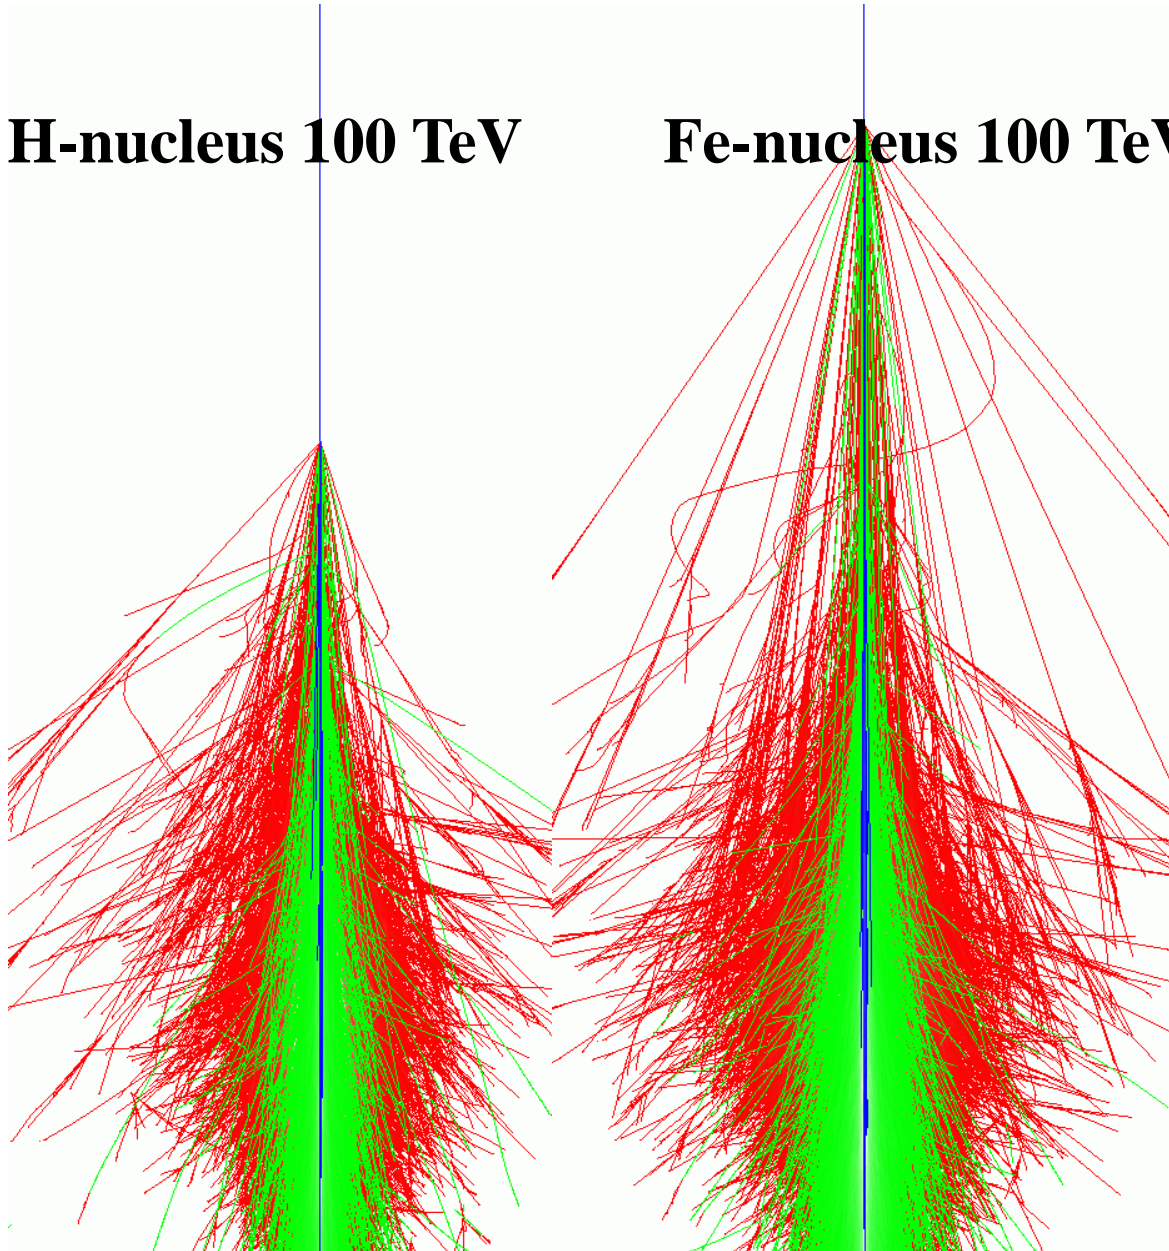

# Extensive Air Showers

**H-nucleus 100 TeV**

**Fe-nucleus 100 TeV**

**Differences at the shower development in the Atmosphere hint to energy und mass of the incident primary particle.**

# EAS – hadronic interactions: nucleus-nucleus

**Superposition model: Fe-nuclei ( $E$ ) = 56 x proton ( $E/56$ ) valid, since binding energy  $\ll$  energy of nucleons ( $< 8\text{MeV} \ll > 100\text{TeV}$ )**

**→ additive observables  $Q$ :  $\langle Q^A(E) \rangle = A \cdot \langle Q^P(E/A) \rangle$**

Fluctuations:  $\sigma_{Q^A}(E) = \sigma_{Q^P}(E/A) / \sqrt{A}$

**increasing  $A$  →**

- more secondary particles with less energy → less electrons (after maximum), more muons
- surviving hadrons have less energy
- larger deflection angles → flatter lateral distributions of the secondary particles

# Extensive Air Showers

Sensitivity to  
energy and mass:  
Particle number and  
particle distributions:  
Longitudinal distributions.

# Extensive Air Showers

Sensitivity to energy und mass:

Particle number and particle distributions: Lateral distributions

# Extensive Air Showers

## Problem: Shower-to-shower Fluctuations

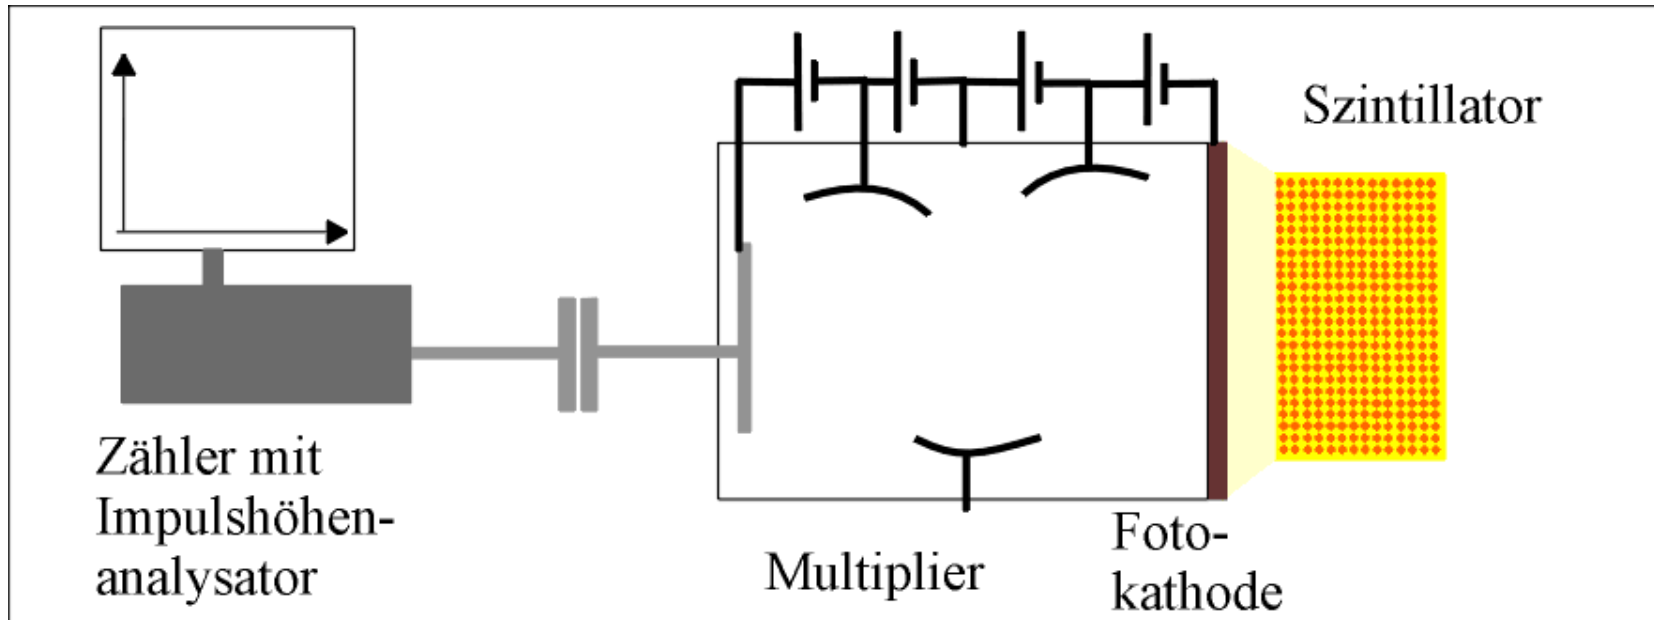

# Measurement Techniques of Air Showers

# Particle Detection: Scintillators

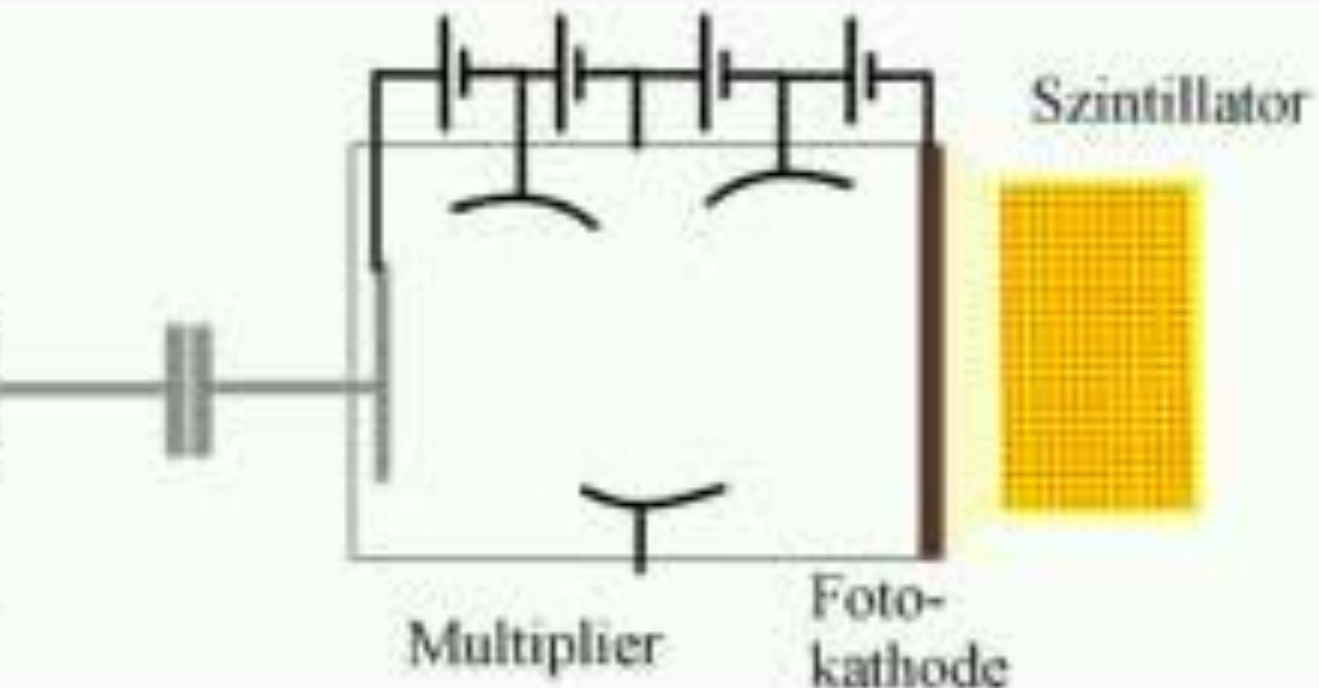

## Scintillation counter:

- Ionizing radiation generates light in the scintillators
- Light generates Electrons (photo effect)
- Electrons are multiplied (PMT)
- Number of electrons (charge) is counted

Zähler mit  
Impulshöhen-  
analysator

Multipliiert  
Fotokathode

# Water Cherenkov Detector

**Pavel Alekseyevich  
Cherenkov  
(1904-1990)**

## Cherenkov-Counter:

- Particle detector for charged particles named after physicist Pavel Cherenkov
- Principle: If the speed of charged particles in a medium exceeds the speed of light in this medium (e.g. water) they emit radiation (in optical light)
- The principle of a Cherenkov counter is based on the detection of this Cherenkov-radiation

# Water Cherenkov Detector

**threshold:**  $\beta = v/c \geq 1/n$

**i.e. Cherenkov-radiation, if  $V_{\text{particle}} > C_{\text{medium}}$**

**In water:  $n = v_{\text{particle}} > 0.75c$ ,**

**i.e. muons  $E_{\text{kin}} > 60\text{MeV}$ , electrons  $E_{\text{kin}} > 0.3\text{MeV}$**

**Fulfilled in air shower particles**

**Angle of emission:**

$$\cos \theta = 1/n\beta \left[ \frac{h}{2p\lambda} (1 - 1/n^2) \right]$$

**photons per track length :**

$$dN/dx = 2\pi\alpha Z^2 \int_{\lambda_1}^{\lambda_2} \lambda^2 (1 - 1/n^2\beta^2) d\lambda/\lambda^2$$

# Fluorescence Light Detection

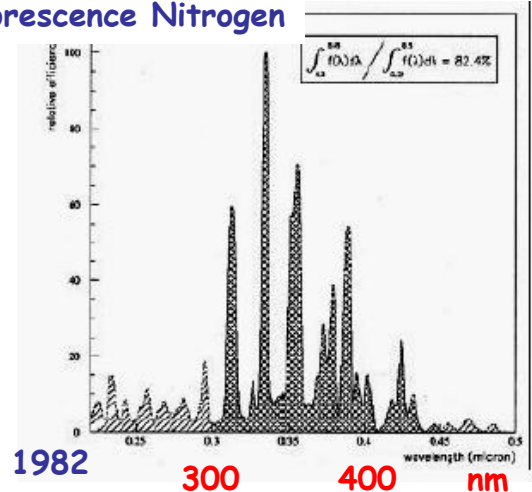

Charged particles excites Nitrogen in atmosphere.

De-excitation: Fluorescence light (isotropic)

## Emission of fluorescence Nitrogen

$\lambda_{abs} \sim 15 \text{ km}$   
 $4 \div 5 \text{ y/m.}$   
 $N_e > 10^8 \text{ e}$   
 $E \sim 10^{18} \text{ eV}$

Fly's Eye Utah 1982

# Radio Detection of EAS

- Characteristic energy for electrons is 30-100 MeV
- Charge separation in Earth's magnetic field  
→ electric dipole
- Gyration of electrons along a small arc  
→ emission of synchrotron radiation
- time varying charge excess in EAS  
→ electric dipole
- atmosphere's refraction index  $\neq 1$   
→ Cherenkov like radio emission
- Electrons are in a shower disk of small thickness  
(2 m < one wavelength at 100 MHz)  
→ coherent emission  
→ beamed into propagation direction
